

Complete the following method **areNeighbors** using Princeton's Graph API. * 8 points
The method should return true if u & v are neighbors.

```
/** Returns true if u & v are neighbors */
public static boolean areNeighbors(Graph g, int u, int v) {
    for (int w : __1__) {
        if (__2__ == u) {
            return __3__;
        }
    }

    return __4__;
}
```

	g.V()	g.adj(v)	v	w	true	false
Blank 1	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Blank 2	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Blank 3	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>
Blank 4	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>

Select all of the following that are true about a graph represented by the following Adjacency Matrix

2 points

$v \backslash w$	0	1	2	3
0	0	1	0	0
1	0	0	0	1
2	1	1	0	0
3	0	0	1	0

- ☐ There is an edge from 2 to 3
- ☐ There is an edge from 3 to 2
- ☐ There is an edge from 0 to itself
- ☐ This is a directed graph

When performing DFS, why do we set `edgeTo[w] = v`?

2 points

```
private void dfs(Graph G, int v) {  
    marked[v] = true;  
    for (int w : G.adj(v)) {  
        if (!marked[w]) {  
            edgeTo[w] = v;  
            dfs(G, w);  
        }  
    }  
}
```

- ☐ To indicate that `v` is our source vertex for the overall DFS traversal
- ☐ To indicate that `v` is the next vertex that should be explored in our DFS traversal
- ☐ To indicate that the path from `s` to `w` includes edge `v→w`
- ☐ To indicate that the path from `s` to `v` includes edge `w→v`

Select all that are true about the `DepthFirstPaths` and `BreadthFirstPaths` algorithms introduced in lecture.

2 points

- ☐ Depth First Paths will return the shortest path from the source to any vertex
- ☐ Breadth First Paths will run asymptotically faster than Depth First Paths
- ☐ When visiting a vertex in Breadth First Paths, we add its unmarked neighbors to a First-In-First-Out queue
- ☐ Breadth First Paths & Depth First Paths are guaranteed to reach the same set of vertices
